LLVM official documentation

llvm.org/docs

A lot of documentation...

Ilvm.org/docs links to:

- 4 references about Design & Overview
- 6 references about Getting Started / Tutorials
- 35 references about User Guides
- 15 references about Programming Documentation
- 40 references about Reference Documentation
- 7 references about Development Process Documentation
- 5 Mailing Lists
- 4 IRC bots

Most of the above references are outdated!

You probably need documentation about the documentation.

Essential documentation

Intro to LLVM Quick and clear introduction to the compiler

> infrastructure. Mostly up-to-date.* [1]

Writing an LLVM pass Explains step by step how to implement a Pass

for those who never did anything like that. [2]

(We will see this tutorial later in the course)

Doxygen

The best code documentation is the code itself.

Sometimes the generated doxygen documen-[3] tation is enough. Updated to the latest development branch, refer to github branches for documentation about the stable versions.

llvm-dev

Canonicalizing Pass Input

We will see the following passes:

Pass	Switch	
Variable promotion	mem2reg	
Loop simplification	loop-simplify	
Loop-closed SSA	lcssa	
Induction variable simplification	indvars	

They are normalization passes:

they convert the code into a canonical form

- Documentation
- Normalization Passes
 Variable Promotion
 Loop Simplification
 Loop-closed SSA
 Induction variable simplification
 Recap
- 3 Analysis Passes
- 4 Conclusions
- 5 Bibliography

One of the most difficult things in compilers is handling memory accesses.

Plain SAXPY (Scalar ax + y)

```
define float @saxpy(float %a, float %x, float %y) {
entry:
  %a.addr = alloca float, align 4
  %x.addr = alloca float, align 4
  %y.addr = alloca float, align 4
  store float %a, float* %a.addr, align 4
  store float %x, float* %x.addr, align 4
  store float %y, float* %y.addr, align 4
  %0 = load float, float* %a.addr, align 4
  %1 = load float, float* %x.addr, align 4
  %mul = fmul float %0. %1
  %2 = load float, float* %y.addr, align 4
  %add = fadd float %mul. %2
  ret float %add
```

Simplifying Representation

In the SAXPY kernel all the variables are allocated on the stack!

Function arguments included!

They are allocated like that because the compiler follows a **conservative** approach:

an instruction could take the address of one of the variables...

However, complex representations make optimizations more difficult:

- suppose you want to compute the a*x+y expression using only one instruction (aka FMA4)
- hard to detect due to load and store

Using Memory Only When Necessary

To limit the number of instructions accessing memory we need to eliminate **load** and **store**

achieved by **promoting** variables from memory to registers

Inside the LLVM-IR:

The mem2reg pass focuses on:

- eliminating allocas used only by load and store instructions
 Also available as a utility function:
 - 11vm::PromoteMemToReg
 - see llvm/Transforms/Utils/PromoteMemToReg.h

Example on simplified code

Starting Point

```
%1 = alloca float
%2 = alloca float
%3 = alloca float
store %a, %1
store %x, %2
store %y, %3
%4 = load %1
%5 = load %2
%6 = fmul %4, %5
%7 = load %3
%8 = fadd %6, %7
ret %8
```

Copy propagation is automatic: replaceAllUsesWith (RAUW) method

Promoting alloca

```
%1 = %a

%2 = %x

%3 = %y

%4 = %1

%5 = %2

%6 = fmul %4, %5

%7 = %3

%8 = fadd %6, %7

ret. %8
```

After Copy-propagation

```
%1 = fmul %a, %x
%2 = fadd %1, %y
ret %2
```

Loop Simplification

Loop-closed SSA Induction variable simplification Recap

- 3 Analysis Passes
- 4 Conclusions
- 5 Bibliography

Loops

There are several kind of loops:

LLVM focuses on one class of loop: **Natural Loops**

Natural Loops

A natural loop:

- has only one entry node the header
- there is a back edge that enters the loop header

Under this definition:

- the irreducible loop example is not a natural loop
- since LLVM consider only natural loops, the irreducible loop example is not recognized as a loop

Loop Terminology

Loops are defined starting from the back-edges:

back-edge edge going back to the loop header: (3,1)

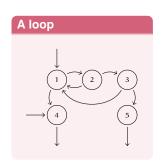

header loop entry node: 1

body nodes that can reach back-edge source node (3) without passing from back-edge target node (1) plus back-edge target

node: $\{1, 2, 3\}$

exiting nodes with a successor outside the loop: {1,3}

exit nodes with a predecessor inside the loop: $\{4,5\}$

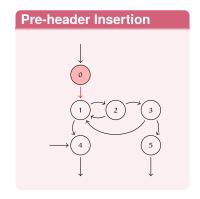

Loop Simplify

Natural loops are

- easy to identify
- not really analysis/optimization friendly!

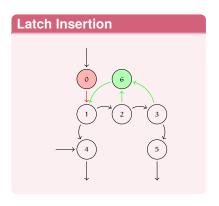

The loop-simplify pass normalizes natural loops:

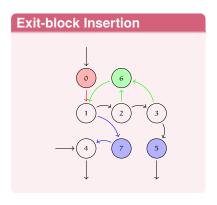

pre-header ensures the loop header has a single entry edge
latch ensures the loop has a single back-edge
exit-block ensures exits dominated by loop header

Loop Simplify

Example

- pre-header always executed before entering the loop
- latch always executed before starting a new iteration
- exit-blocks executed only after exiting the loop

- Documentation
- 2 Normalization Passes

Variable Promotion Loop Simplification

Loop-closed SSA

Induction variable simplification Recap

- 3 Analysis Passes
- 4 Conclusions
- 5 Bibliography

Loop representation can be further normalized:

- loop-simplify normalizes the **shape** of the loop *(control flow)*
- it does not involve the instructions in the loop (data flow)

Keeping SSA form is expensive with loops:

 Any optimization involving an SSA variable defined inside the loop, and used outside the loop, causes a ripple effect!

The lossa transformation is the solution:

- inserts phi instructions at loop boundaries
- now, optimizations performed inside the loop do not affect the code outside of it

Example

Linear Search

```
int *search(int *x, int n, int y)
{
  int j = -1;
  for (int i = 0; i < n; i++)
    if (x[i] == y)
        j = i;
  return j;
}</pre>
```

The example is trivial, this transformation is mostly useful for *large loop bodies*.

Example

Before LCSSA

```
for.cond:
  \%j.0 = phi i32 [ -1, %entry ], [ %j.1, %for.inc ]
  %i.0 = phi i32 [ 0, %entry ], [ %inc, %for.inc ]
  %cmp = icmp slt i32 %i.0, %n
  br i1 %cmp, label %for.body, label %for.end
for.body:
  [...]
if.end:
  \%j.1 = phi i32 [ %i.0, %if.then ], [ %j.0, %for.body ]
  br label %for.inc
for.inc:
  %inc = add nsw i32 %i.0, 1
  br label %for.cond
for end:
  ret i32 %j.0
```

Example

After LCSSA

```
for . cond:
  \%j.0 = phi i32 [ -1, %entry ], [ %j.1, %for.inc ]
  %i.0 = phi i32 [ 0, %entry ], [ %inc, %for.inc ]
  %cmp = icmp slt i32 %i.0. %n
  br i1 %cmp, label %for.body, label %for.end
for.body:
  Γ...1
if.end:
  \%j.1 = phi i32 [ %i.0, %if.then ], [ %j.0, %for.body ]
  br label %for inc
for inc:
  %inc = add nsw i32 %i.0.1
  br label %for.cond
for.end:
  %j.0.lcssa = phi i32 [ %j.0, %for.cond ]
  ret i32 %i.0.1cssa
```

Induction Variables

Some loop variables are special:

. e.g. counters

The generalization of this intuition are **induction variables**:

 foo is a loop induction variable if its successive values form an arithmetic progression:

$$foo = bar * baz + biz$$

where: bar, biz are loop-invariant *,
baz is an induction variable

 foo is a canonical induction variable if it is always incremented by a constant amount:

$$foo = foo + biz$$

where biz is loop-invariant

^{*}Constants inside the loop

Induction Variable Simplification

Canonical induction variables are often used to drive loop execution.

Given a loop, the indvars pass tries to transform its induction variables into **canonical** induction variables.

- It also transforms loop exit conditions in simple inequalities
- Definition of other variables derived from the induction variables are moved outside the loop if used there

LLVM defines canonical induction variables as:

- initialized to 0
- incremented by 1 at each loop iteration

- **Documentation**
- **Normalization Passes**

Loop-closed SSA

- Recap

- Conclusions
- **Bibliography**

Normalization

Wrap-up

"Standard" running order:

- mem2reg: limits use of memory
- 2 loop-simplify: canonicalizes loops
 - Improved detection of a lot of standard patterns!
- 3 lcssa: keeps effects of subsequent loop optimizations local limits overhead of maintaining SSA form
- indvars: normalizes induction variables simplifies and highlightsthe loop condition

For more normalization passes:

try running opt -help

 Scalar Evolution
 Alias Analysis
 Memory SSA
- 4 Conclusions
- 5 Bibliography

Checking Input Properties

Analyses basically allow to:

- derive information and properties of the input
- verify properties of input

Keeping analyzed information updated is expensive:

- tuned algorithms update information when an optimization invalidates it
- incrementally updating analyses are cheaper than recomputing them

As an **optimization**, many LLVM analysis supports incremental updates.

Useful Analyses

We will see the following passes:

Pass	Switch	Transitive
Dominator tree	domtree	No
Post-dominator tree	postdomtree	No
Loop information	loops	Yes
Scalar evolution	scalar-evolution	Yes
Alias analysis	_	Yes
Memory SSA	memoryssa	Yes

Requesting an Analysis

Your pass needs to tell the pass manager which analyses it needs!

Transitive analyses:

11vm::AnalysisUsage::addRequiredTransitive<T>()

Non-transitive analyses:

11vm::AnalysisUsage::addRequired<T>()

For **chained analyses***, the addRequiredTransitive method should be used instead of the addRequired method.

This informs the PassManager that the transitively required pass should be alive as long as the requiring pass is.

^{*}Analyses that use the result of another analysis

- 1 Documentation
- 2 Normalization Passes

Dominance Trees

Dominance trees answer to control-related queries:

is A executed **before** B? is A executed **after** B?
$$\Downarrow$$
 11vm::DominatorTree 11vm::PostDominatorTree

The interfaces of these two trees is mostly the same:

- bool dominates(A, B)
- bool properlyDominates(A, B)

A and B are either llvm::BasicBlocks or llvm::Instructions

By using opt, it is possible to show the trees:

- -view-dom, -dot-dom
- -view-postdom, -dot-postdom

- 1 Documentation
- 2 Normalization Passes
- 3 Analysis Passes
 Dominance Trees
 Loop Information
 Scalar Evolution
 Alias Analysis
 Memory SSA
- 4 Conclusions
- 5 Bibliography

Loop Information

Loop information is represented using two classes:

11vm::Loop Represents a single loop in a function.
Contained inside a 11vm::LoopInfo.

Using 11vm::LoopInfo it is possible to:

- navigate through top-level loops:
 - llvm::LoopInfo::begin()
 - llvm::LoopInfo::end()
- get the loop for a given basic block:
 - llvm::LoopInfo::operator[](llvm::BasicBlock *)

Loop Information

Nesting Tree

Loops are represented as a tree:

```
Loop Hierarchy

1
2
4
```

```
children loops llvm::Loop::begin(), end()
parent loop llvm::Loop::getParentLoop()
```

Loop Information

Query Loops

```
Accessors for important nodes:
 pre-header llvm::Loop::getLoopPreheader()
    header llvm::Loop::getHeader()
      latch 11vm::Loop::getLoopLatch()
     exiting llvm::Loop::getExitingBlock(),
            11vm::Loop::getExitingBlocks(...)
       exit 11vm::Loop::getExitBlock()
            11vm::Loop::getExitBlocks(...)
The list of all BBs in the loop is accessible via:
   iterators llvm::Loop::block_begin(),
            11vm::Loop::block end()
     vector std::vector<BasicBlock *> &Loop::getBlocks()
```

Contents

 Dominance Trees
 Loop Information
 Scalar Evolution
 Alias Analysis
 Memory SSA
- 4 Conclusions
- 5 Bibliography

The **SC**alar **EV**olution pass analyzes scalar expressions inside loops.

- all expressions are categorized and represented uniformly
- is capable of handling general induction variables
- also useful outside of loops
- opt flags: -analyze -scalar-evolution

Example

```
for.cond:
    %i.0 = phi [ 0, %entry ], [ %i.inc, %for.inc ]
    %cond = icmp ne %i.0, 10
    br %cond, label %for.body, label %for.end
for.inc:
    %i.inc = add nsw %i.0, 1
    br label %for.cond
for.end:
...
```

SCEV for %i.0:

- initial value 0
- incremented by 1 at each iteration
- final value 10

Example

Source

```
void foo() {
  int bar[10][20];

for(int i = 0; i < 10; ++i)
    for(int j = 0; j < 20; ++j)
      bar[i][j] = 0;
}</pre>
```

SCEV {A,B,C}<%D>:

- A starting value
- B operator
- C stride
- D loop head BB {0,+,1}=0+1+1+1+...

Induction Variables

```
%i.0 = phi i32 [ 0, %entry ], [ %inc6, %for.inc5 ]
--> {0,+,1}<nuw><nsw><%for.cond> Exits: 10
%j.0 = phi i32 [ 0, %for.body ], [ %inc, %for.inc ]
--> {0,+,1}<nuw><nsw><%for.cond1> Exits: 20
```

More than Induction Variables

The scalar evolution framework manages any scalar expression:

Pointer SCEVs in two nested loops

```
%arrayidx = getelementptr {...} %bar, i32 0, i32 %i.0
--> {%bar,+,80}<nsw><%for.cond>
Exits: {%bar,+,80}<nsw><%for.cond>

%arrayidx4 = getelementptr {...} %arrayidx, i32 0, i32 %j.0
--> {{%bar,+,80}<nsw><%for.cond>,+,4}<nsw><%for.cond1>
Exits: {(80 + %bar),+,80}<nsw><%for.cond>
```

SCEV is an analysis used by many common optimizations

- induction variable substitution
- strength reduction
- vectorization
- ...

SCEVs Design

SCEVs are modeled by the 11vm::SCEV class:

- a subclass for each kind of SCEV: e.g. 11vm::SCEVAddExpr
- instantiation disabled

A SCEV actually is a tree of SCEVs:

```
• {(80 + %bar),+,80} =
```

•
$$%1 = 80 + \%bar$$

Tree leaves:

```
constant 11vm::SCEVConstant: e.g. 80
unknown* 11vm::SCEVUnknown: e.g. %bar
```

SCEV tree explorable through the visitor pattern:

• 11vm::SCEVVisitor

^{*}Not further splittable

Analysis Interface

The llvm::ScalarEvolutionAnalysis pass computes all the SCEVs for a given llvm::Function.

The llvm::ScalarEvolution instance produced by the pass provides the following services:

- get the SCEV representing a value:
 - getSCEV(llvm::Value *)
- get important SCEVs from other structures or SCEVs:

```
• getBackedgeTakenCount(11vm::Loop *)
```

- getPointerBase(11vm::SCEV *)
- · ...
- create new SCEVs explicitly:
 - getConstant(llvm::ConstantInt *)
 - getAddExpr(llvm::SCEV *, llvm::SCEV *)
 - ...

Let *X* be an instruction accessing a memory location:

is there another instruction accessing the same location?

Alias analysis tries to answer the question:

application optimization of memory operations
problem often fails

Interface of the system: llvm::AAResults

Requiring Alias Analysis

AU.addRequiredTransitive<AAResultsWrapperPass>();

Chained Analysis

AA is actually a chain of multiple analyses, executed in sequence:

```
    Basic Alias Analysis (basicaa)
```

...

nth. Type Based Alias Analysis (tbaa)*

...

last. Dummy Alias Analysis (noaa)

Every analysis in the chain fills the gap left by the previous analyses.

^{*}AKA the evil alias analysis

Memory Representation

Source

%1 = load i16, i16* %a %2 = load i16, i16* %b store i16 %2, i32* %a store i16 %1, i32* %b

Basic building block: 11vm::MemoryLocation

Encapsulates a tuple: (address, size)

Can be computed from a llvm::Value

Distinct Locations

Overlapping Locations

Same Location

Basic Interface

Given two memory locations X, Y, the alias analyzer classifies them:

- llvm::AliasResult::NoAlias
 X and Y are different memory locations
- llvm::AliasResult::MustAlias

 X and Y are equal i.e. they points to the same address
- 11vm::A1iasResult::PartialA1ias
 X and Y partially overlap i.e. they points to different addresses, but the pointed memory areas partially overlap
- llvm::AliasResult::MayAlias unable to compute aliasing information yet – i.e. X and Y can be different locations, or X can be a complete/partial alias of Y

Queries performed using:

• llvm::AAResults::alias(X, Y)

Basic Interface

A different categorization involves whether an instruction I **reads** and/or modifies a memory location *X*:

11vm::ModRefInfo::NoModRef
 The access neither references nor modifies the value stored in X

11vm::ModRefInfo::Ref
 The access may reference the value stored in X

11vm::ModRefInfo::Mod
 The access may modify the value stored in X

11vm::ModRefInfo::ModRef
 The access may reference and may modify the value stored in X

Queries performed using:

• llvm::AAResults::getModRefInfo(I, X)

Mid-level Interface

This interface is very low-level!

What if we wanted to compute all aliases of a single value X?

To do this, LLVM provides the llvm::AliasSet class:

- instantiate a new llvm::AliasSetTracker starting from llvm::AAResults*
- 2 it builds (one or more) llvm::AliasSet

For a given location X, a 11vm::AliasSet:

contains all locations aliasing with X

Alias Set Memory Accesses

Alias sets return memory reference and aliasing information just like the low-level interface.

Warning: This information is **less precise**, as it is derived by **conservatively aggregating** more detailed data!

- bool llvm::AliasSet::isRef()
 memory accessed in read-mode e.g. a load is inside the set
- bool llvm::AliasSet::isMod()
 memory accessed in write-mode e.g. a store is inside the set
- bool llvm::AliasSet::isMustAlias()
 all pointers in the set MustAlias with each other
- bool llvm::AliasSet::isMayAlias()
 at least one pair of pointer is not a MustAlias pair

Mid-level Interface

Entry point is llvm::AliasSetTracker::getAliasSetFor(...)

Only argument is a reference to 11vm::MemoryLocation

Once you have the llvm::AliasSet you can inspect the list of memory locations in it with the standard C++ iterator pattern:

size(), begin(), end()

Memory SSA

Alias Analyzer High-level Interface

The llvm::MemorySSAAnalysis pass wraps alias analysis to answer queries in the following form:

 let %foo be an instruction accessing memory. Which preceding instructions does %foo depends on?

This is done by representing all memory accesses in a **SSA-like form**:

- store-like instructions become definitions (MemoryDef)
- load-like instructions become uses (MemoryUse)
- stores to the same location in parallel CFG branches become phis (MemoryPhi)

Memory Dependence Analysis

MemorySSA "instructions" are owned by 11vm::MemorySSA objects.

They are **overlaid** on top of the normal CFG.

- AccessList *getBlockAccesses(BasicBlock *)
- DefsList *getBlockDefs(BasicBlock *)

This basic interface is very hard to use:

- 11vm::MemorySSAWalker provides support for the most common query
- MemoryAccess *getClobberingMemoryAccess(...)
 - Returns the nearest dominating memory access that clobbers the same memory location given.
