LLVM official documentation

llvm.org/docs

A lot of documentation...

11vm.org/docs mentions:

- 5 references about *Design & Overview*
- 23 references about *User Guides*
- 15 references about Programming Documentation
- 42 references about Subsystem Documentation
- 9 references about Development Process Documentation
- 5 Mailing Lists
- 5 IRC bots

Most of the above references are OUT-OF-DATE.

You probably need documentation about the documentation itself.

Essential documentation

- Intro to LLVM [?] gives a quick and clear introduction to the compiler infrastructure. It is mostly up-to-date.¹
- Writing an LLVM pass [?] explains step by step how to implement a Pass for those who never did anything like that. We will see this tutorial later in the course.
 - Doxygen [?] The best code documentation is the code itself.

 Sometimes the generated doxygen documentation is enough. It also contains links to the web version of the source code. It is updated to the latest development branch. Please refer to github branches for the documentation about the stable versions.
 - Ilvm-dev Mailing List. Last resource: ask other developers. Warning: 24/7 many people are posting in this ML.

¹at the time I am writing

Canonicalize Pass Input

We will see the following passes:

Pass	Switch
Variable promotion	mem2reg
Loop simplify	loop-simplify
Loop-closed SSA	lcssa
Induction variable simplification	indvars

They are normalization passes:

put data into a canonical form

One of the most difficult things in compiler is:

considering memory accesses

Plain SAXPY

```
define float @saxpy(float %a, float %x, float %y) {
entry:
    %a.addr = alloca float, align 4
    %x.addr = alloca float, align 4
    %y.addr = alloca float, align 4
    store float %a, float* %a.addr, align 4
    store float %x, float* %x.addr, align 4
    store float %y, float* %y.addr, align 4
    %0 = load float, float* %a.addr, align 4
    %1 = load float, float* %a.addr, align 4
    %mul = fmul float %0, %1
    %2 = load float, float* %y.addr, align 4
    %add = fadd float %mul, %2
    ret float %add
}
```

Simplifying Representation

In the SAXPY kernel some alloca are generated:

• represent local variables ²

They are generated due to compiler conservative approach:

• maybe some instruction can take the addresses of such variables, hence a memory location is needed

Complex representations makes hard performing further actions:

- suppose you want to compute a * x + y using only one instruction 3
- hard to detect due to load and store

²Arguments are considered local variables

³e.g. FMA4

Using Memory Only When Necessary

To limit the number of instruction accessing memory:

- we need to eliminate load and store
- achieved by promoting variables from memory to registers

Inside LLVM SSA-based representation:

```
memory Stack allocations - e.g %1 = alloca float, align 4 register SSA variables - e.g. %a
```

The mem2reg pass focus on:

eliminating alloca with only load and store uses

Also available as utility:

11vm::PromoteMemToReg⁴

⁴see lib/Transforms/Utils/PromoteMemoryToRegister.cpp

Example on simplified code

Starting Point

```
%1 = alloca float

%2 = alloca float

%3 = alloca float

store %a, %1

store %x, %2

store %y, %3

%4 = load %1

%5 = load %2

%6 = fmul %4, %5

%7 = load %3

%8 = fadd %6, %7

ret %8
```

Copy propagation performed transparently by the compiler

Promoting alloca

```
%1 = %a

%2 = %x

%3 = %y

%4 = %1

%5 = %2

%6 = fmul %4, %5

%7 = %3

%8 = fadd %6, %7

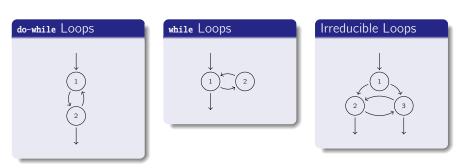

ret %8
```

After Copy-propagation

```
%1 = fmul %a, %x
%2 = fadd %1, %y
ret %2
```

Loops

Different kind of loops:

In LLVM the focus is on one kind of loop:

natural loops

Natural Loops

A natural loop:

- has only one entry node header
- there is a back edge that enter the loop header

Under this definition:

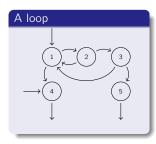

- the irreducible loop is not a natural loop
- since LLVM consider only natural loops, the irreducible loop is not recognized as a loop

Loop Terminology

Loops defined starting from back-edges:

back-edge edge entering loop header: (3, 1)

header loop entry node: 1
body nodes that can reach
back-edge source node (3)
without passing from
back-edge target node (1)
plus back-edge target node:
{1,2,3}

exiting nodes with a successor outside the loop: {1, 3}

exit nodes with a predecessor inside the loop: {4,5}

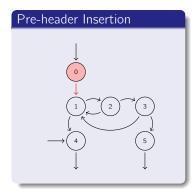

Loop Simplify

Natural loops finding is the base pass identify loops, but:

• some features are not analysis/optimization friendly

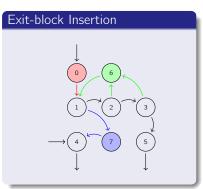

The loop-simplify pass normalize natural loops:

pre-header the only predecessor of header node
latch the starting node of the only back-edge
exit-block ensures exits
dominated by loop
header

Loop Simplify

Example

- pre-header always executed before entering the loop
- latch always executed before starting a new iteration
- exit-blocks always executed after exiting the loop

Loop representation can be further normalized:

- loop-simplify normalize the shape of the loop
- nothing is said about loop definitions

Keeping SSA form is expensive with loops:

- 1cssa insert phi instruction at loop boundaries for variables defined inside the loop body and used outside
- this guarantees isolation between optimization performed inside and outside the loop
- faster keeping IR into SSA form propagation of code changes outside the loop blocked by phi instructions

Example

Linear Search

```
unsigned search(float *x, unsigned n, float y) {
  unsigned i, j = 0;
  for(i = 0; i != n; ++i)
    if(x[i] == y)
        j = i;
  return j;
}
```

The example is trivial:

- think about having large loop bodies
- transformation becomes useful

Example

Before LCSSA

```
for.cond:
  %i.0 = phi i32 [ 0, %entry ], [ %inc, %for.inc ]
  %j.0 = phi i32 [ 0, %entry ], [ %j.1, %for.inc ]
  %cmp = icmp ne i32 %i.0, %n
  br i1 %cmp, label %for,body, label %for,end
  . . .
if.end:
  %j.1 = phi i32 [ %i.0, %if.then ], [ %j.0, %for.body ]
  br label %for inc
for inc:
  %inc = add i32 %i.0. 1
  br label %for.cond
for end:
 ret i32 %j.0
```

Example

After LCSSA

```
for.cond:
  %i.0 = phi i32 [ 0, %entry ], [ %inc, %for.inc ]
  %j.0 = phi i32 [ 0, %entry ], [ %j.1, %for.inc ]
  %cmp = icmp ne i32 %i.0, %n
  br i1 %cmp, label %for.body, label %for.end
  . . .
if.end:
  %j.1 = phi i32 [ %i.0, %if.then ], [ %j.0, %for.body ]
  br label %for.inc
for inc:
  %inc = add i32 %i.0, 1
  br label %for cond
for . end:
  %j.0.lcssa = phi i32 [ %j.0, %for.cond ]
 ret i32 %j.0.1cssa
```

Induction Variables

Some loop variables are special:

• e.g. counters

Generalization lead to induction variables:

• foo is a loop induction variable if its successive values form an arithmetic progression:

$$foo = bar * baz + biz$$

where bar, biz are loop-invariant ⁵, and baz is an induction variable

 foo is a canonical induction variable if it is always incremented by a constant amount:

$$foo = foo + hiz$$

where biz is loop-invariant

⁵Constants inside the loop

Induction Variable Simplification

Canonical induction variables are used to drive loop execution:

 given a loop, the indvars pass tries to find its canonical induction variable

With respect to theory, LLVM canonical induction variable is:

- initialized to o
- incremented by 1 at each loop iteration

Normalization

Wrap-up

Normalization passes running order:

- mem2reg: limit use of memory, increasing the effectiveness of subsequent passes
- loop-simplify: canonicalize loop shape, lower burden of writing passes
- 1cssa: keep effects of subsequent loop optimizations local, limiting overhead of maintaining SSA form
- indvars: normalize induction variables, highlighting the canonical induction variable

Other normalization passes available:

• try running opt -help

Contents

Checking Input Properties

Analysis basically allows to:

- derive information and properties of the input
- verify properties of input

Keeping analysis information is expensive:

- tuned algorithms updates analysis information when an optimization invalidates them
- incrementally updating analysis is cheaper than recomputing them

Many LLVM analysis supports incremental updates:

- this is an optimization
- focus on information provided by analysis

Useful Analysis

We will see the following passes:

Analysis

Pass	Switch	Transitive
Control flow graph	none	No
Dominator tree	domtree	No
Post-dominator tree	postdomtree	No
Loop information	loops	Yes
Scalar evolution	scalar-evolution	Yes
Alias analysis	special	Yes
Memory dependence	memdep	Yes

Require Analysis

Ask the pass manager to schedule a specific pass before running the current one.

Requiring analysis by transitivity:

```
yeS 11vm::AnalysisUsage::addRequiredTransitive<T>()
NO 11vm::AnalysisUsage::addRequired<T>()
```

In cases where analyses chain, the addRequiredTransitive method should be used instead of the addRequired method.

This informs the PassManager that the transitively required pass should be alive as long as the requiring pass is.

The Control Flow Graph is implicitly maintained by LLVM:

• no specific pass to build it

Recap:

- CFG for a function is a set of basic blocks
- a basic block is a set of instructions

Functions and basic blocks acts like containers:

- STL-like accessors: front(), back(), size(), ...
- STL-like iterators: begin(), end()

Each contained element is aware of its container:

getParent()

Walking

Every CFG has an entry basic block:

- the first executed basic block
- it is the root/source of the graph
- get it With llvm::Function::getEntryBlock()

More than one exit blocks can be generated:

- their terminator instructions are rets
- they are the leaves/sinks of the graph
- USE llvm::BasicBlock::getTerminator() to get the terminator . . .
- ...then check its real class

Side Note

Casting Framework

For performance reasons, a custom casting framework is used:

 you cannot use static_cast and dynamic_cast with types/classes provided by LLVM

LLVM Casting Functions

Meaning	Function
Static cast of y * to x *	X * llvm::cast <x>(Y *)</x>
Dynamic cast of Y * to X *	<pre>X * 11vm::dyn_cast<x>(Y *)</x></pre>
ls y an x?	bool llvm::isa <x>(Y *)</x>

Example:

● is BB a sink?

llvm::isa<llvm::ReturnInst>(BB.getTerminator())

Basic Blocks

Every basic block BB has one or more:

```
predecessors from pred_begin(BB) to pred_end(BB) 6
SUCCESSORS from succ_begin(BB) to succ_end(BB)
```

Convenience accessors directly available in llvm::BasicBlock:

• C.Q. llvm::BasicBlock::getUniquePredecessor()

Other convenience member functions:

- moving a basic block: llvm::BasicBlock::moveBefore(llvm::BasicBlock *) Or llvm::BasicBlock::moveAfter(llvm::BasicBlock *)
- split a basic block:

```
llvm::BasicBlock::splitBasicBlock(llvm::BasicBlock::iterator)
```

. . .

⁶see include/Ilvm/IR/CFG.h

Instructions

The llvm::Instruction class define common operations:

• e.g. getting an operand: llvm::Instruction::getOperand(unsigned)

Subclasses provide specialized accessors:

 e.g the load instruction takes an operand that is a pointer: llvm::LoadInst::getPointerOperand()

Instructions

The 11vm::Instruction class define common operations:

• e.g. getting an operand: llvm::Instruction::getOperand(unsigned)

Subclasses provide specialized accessors:

 e.g the load instruction takes an operand that is a pointer: llvm::LoadInst::getPointerOperand()

The value produced by the instruction is the instruction itself:

Example

Consider:

```
%6 = load i32, i32* %1, align 4
```

the load is described by an instance of llvm::LoadInst. That instance also models the %6 variable

Instructions

Creating New Instructions

Instructions built using:

- CONSTRUCTORS e.g. llvm::LoadInst::LoadInst(...)
- factory methods e.g. llvm::GetElementPtrInst::Create(...)

Interface is not homogeneous:

- some instructions support both methods
- others support only one

At build-time, instructions can be:

- appended to a basic block
- inserted after/before a given instruction

Insertion point usually specified as builder last argument

Side Note

Definitions and Uses

LLVM class hierarchy is built around two simple concepts:

value something that can be used: 11vm::Value

user something that can use: 11vm::User

A value is a definition:

• 11vm::Value::use_begin(), 11vm::Value::use_end() to Visit Uses 7

An user access definitions:

• llvm::User::op_begin(), llvm::User::op_end() to visit used values 8

Functions:

- used by call sites
- uses formal parameters

Instructions:

- define an SSA value
- uses operands

⁷llvm::Instruction derives from llvm::Value

⁸¹¹vm::Value derives from 11vm::User

Side Note

Value Typing

Every 11vm::Value is typed:

• USE llvm::Value::getType() to get the type

Since every instructions is/define a value:

instructions are typed

Example

Consider:

```
%6 = load i32, i32* %1, align 4
```

- The %6 variable actually is the instruction itself
- Its type is the type of load return value, i32

Dominance Trees

Dominance trees answer to control-related queries:

- is this basic block executed before that?
- 11vm::DominatorTree

- is this basic block executed after that?
- 1lvm::PostDominatorTree

The two trees interface is similar:

- bool dominates(X *, X *)
- bool properlyDominates(X *, X *)

Where x is an llvm::BasicBlock Or an llvm::Instruction

by using opt, it is possible print them:

- -view-dom, -dot-dom
- -view-postdom, -dot-postdom

Loop Information

Loop information are represented using two classes:

- 11vm::LoopInfo analysis detects natural loops
- 11vm::Loop represents a single loop

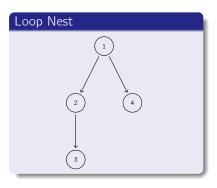

Using 11vm::LoopInfo it is possible:

- navigate through top-level loops:
 - llvm::LoopInfo::begin(), llvm::LoopInfo::end()
- get the loop for a given basic block:
 - llvm::LoopInfo::operator[](llvm::BasicBlock *)

Loop Information

Nesting Tree

Loops are represented in a nesting tree:

Nest navigation:

- children loops: 11vm::Loop::begin(), 11vm::Loop::end()
- parent loop: 11vm::Loop::getParentLoop()

Loop Information

Query Loops

Accessors for relevant nodes also available:

```
pre-header 11vm::Loop::getLoopPreheader()
       header 11vm::Loop::getHeader()
         latch 11vm::Loop::getLoopLatch()
       exiting llvm::Loop::getExitingBlock(),
                llvm::Loop::getExitingBlocks(...)
           exit llvm::Loop::getExitBlock()
                llvm::Loop::getExitBlocks(...)
Loop basic blocks accessible via:
     iterators 11vm::Loop::block_begin(),
                llvm::Loop::block end()
        Vector std::vector<llvm::BasicBlock *> &llvm::Loop::getBlocks()
```

The SCalar EVolution framework:

- represents scalar expressions
- supports recursive updates
- lower burden of explicitly handling expressions composition
- is designed to support general induction variables

for.cond: %i.0 = phi [0, %entry], [%i.inc, %for.inc] %cond = icmp ne %i.0, 10 br %cond, label %for.body, label %for.end for.inc: %i.inc = add nsw %i.0, 1 br label %for.cond for.end: ...

SCEV for %i.0:

- initial value 0
- incremented
- by 1 at each iteration
- final value 10

Example

Source

```
void foo() {
  int bar[10][20];

for(int i = 0; i < 10; ++i)
   for(int j = 0; j < 20; ++j)
    bar[i][j] = 0;
}</pre>
```

SCEV $\{A,B,C\}<\%D>$:

- A initial
- в operator
- c operand

Induction Variables

```
%i.0 = phi i32 [ 0, %entry ], [ %inc6, %for.inc5 ]
--> {0,+,1}<nuw><nsw><%for.cond> Exits: 10
%j.0 = phi i32 [ 0, %for.body ], [ %inc, %for.inc ]
--> {0,+,1}<nuw><nsw><%for.cond1> Exits: 20
```

More than Induction Variables

The scalar evolution framework manages any scalar expression:

Pointer SCEVs

```
%arrayidx = getelementptr {...} %bar, i32 0, i32 %i.0
--> {%bar,+,80}<nsw><%for.cond>
Exits: {%bar,+,80}<nsw><%for.cond>

%arrayidx4 = getelementptr {...} %arrayidx, i32 0, i32 %j.0
--> {{%bar,+,80}<nsw><%for.cond>,+,4}<nsw><%for.cond1>
Exits: {(80 + %bar),+,80}<nsw><%for.cond>
```

SCEV is an analysis used for common optimizations:

- induction variable substitution
- strength reduction
- vectorization
- . . .

Scalar Evolution SCEVs Design

SCEVs are modeled by the <code>llvm::scev</code> class:

- a subclass for each kind of SCEV: e.g. 11vm::scevAddExpr
- instantiation disabled

A SCEV actually is a tree of SCEVs:

$$\bullet$$
 {(80 + %bar).+.80} = {%1.+.80}. %1 = 80 + %bar

Tree leaves:

```
constant 11vm::SCEVConstant: e.g. 80 unknown 9 11vm::SCEVUnknown: e.g. %bar
```

SCEV tree explorable through the visitor pattern:

11vm::SCEVVisitor

⁹Not further splittable

Analysis Interface

The 11vm::ScalarEvolution class:

- analyzes SCEVs for a 11vm::Function
- builds SCEVs for values:

```
llvm::ScalarEvolution::getSCEV(llvm::Value *)
```

creates new SCEVs:

```
llvm::ScalarEvolution::getConstant(llvm::ConstantInt *)
llvm::ScalarEvolution::getAddExpr(llvm::SCEV *, llvm::SCEV *)
...
```

gets important SCEVs:

```
llvm::ScalarEvolution::getBackedgeTakenCount(1lvm::Loop *)
llvm::ScalarEvolution::getPointerBase(1lvm::SCEV *)
...
```

Alias Analysis

Let X be an instruction accessing a memory location:

• is there another instruction accessing the same location?

Alias analysis tries to answer the question:

```
application memory operation scheduling problem often fails
```

Different algorithms for alias analysis:

- common interface 11vm::AliasAnalysis for all algorithms
- by default, basic alias analyzer basicaa is used

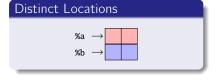

Requiring Alias Analysis

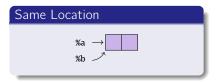

```
AU.addRequiredTransitive<llvm::AliasAnalysis>();
```

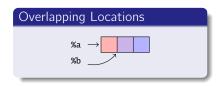

Alias Analysis

Memory Representation

%1 = load i16, i16* %a %2 = load i16, i16* %b store i16 %2, i32* %a store i16 %1, i32* %b

Basic building block is 11vm::AliasAnalysis::Location:

- address: e.g. %a
- size: e.g. 2 bytes

Basic Interface

Given two locations X, Y, the alias analyzer classifies them:

- llvm::AliasAnalyzer::NoAlias: X and Y are different memory locations
- ilvm::AliasAnalyzer::MustAlias: X and Y are equal i.e. they points to
 the same address
- llvm::AliasAnalyzer::PartialAlias: X and Y partially overlap i.e. they points to different addresses, but the pointed memory areas partially overlap
- 11vm::AliasAnalyzer::MayAlias: unable to compute aliasing information

 i.e. X and Y can be different locations, or X can be a complete/partial alias of Y

Queries performed using:

1lvm::AliasAnalyzer::alias(X, Y)

Mid-level Interface

Basic alias analyzer interface is low-level – we would like expressing

- how referenced memory location is accessed?
- which other instructions reference the same location?

What we need is a set, to classify memory locations:

- CONSTRUCT a llvm::AliasSetTracker starting from a llvm::AliasAnalyer *
- it builds (one or more) 11vm::AliasSet

For a given location X, a 11vm::AliasSet:

queries about a single pointer X:

contains all locations aliasing with X

Alias Set Memory Accesses

Each alias set references the memory:

- llvm::AliasSet::NoModRef: no memory reference i.e. the set is empty
- 11vm::Aliasset::Mod: memory accessed in write-mode e.g. a store is inside the set
- 1lvm::AliasSet::Ref: memory accessed in read-mode e.g. a load is inside the set
- llvm::AliasSet::ModRef: memory accessed in read-write mode e.g. a load and a store inside the set

Mid-level Interface

Entry point is 11vm::AliasSetTracker::getAliasSetForPointer(...):

- 11vm::Value *: location address
- uint64 t: location size
- 11vm::MDNode *: used for type-based alias analysis 10
- bool *: whether a new llvm::AliasSet has been created to hold the location location does not alias up to now

Having the 11vm::AliasSet:

- STL container-like interface: size(), begin(), end(), ...
- check reference type: llvm::AliasSet::isRef(), ...
- check aliasing type: llvm::AliasSet::isMustAlias(), ...

¹⁰set to NULL

Memory Dependence Analysis

Alias Analyzer High-level Interface

The <code>llvm::MemoryDependenceAnalysis</code> wraps alias analysis to answer queries in the following form:

• let %foo be an instruction accessing memory. Which preceding instructions does %foo depends on?

Reads:

 store instructions writing memory locations aliases with the one references by %foo

Writes:

 load instructionss reading memory locations aliased with the one referenced by %foo

Memory Dependence Analysis

Let %foo be a llvm::Instruction accessing memory:

- Call llvm::MemoryDependenceAnalysis::getDependency(...)
- YOU get a llvm::MemDepResult

Dependencies are classified:

APIs

- llvm::MemDepResult::isclobber(): an instruction clobbering i.e. potentially modifying location referenced by %foo has been found
- llvm::MemDepResult::isDef(): an instruction defining e.g. writing the exact location referenced by %foo has been found
- ilvm::MemDepResult::isNonLocal(): no dependency found on %foo basic block
- 1lvm::MemDepResult::isNonFuncLocal(): no dependency found on %foo function

Contents

Conclusions

Inside LLVM there a lot of passes: normalization put program into a canonical form

Please remember that

• a good compiler writer re-uses code

analysis get info about program

check LLVM sources before re-implementing a pass
